RESUMEN

The research group "**Química (bio)Analítica y Circular**" (**bioCir**) of the **University of Alicante** has developed a **mobile, compact and autonomous unit** for the *in situ* processing of fresh plant biomass and agricultural by-products, making it possible to obtain high-value bioactive extracts directly at the place of cultivation or where the residue is generated.

The technology integrates within a single transportable platform all the stages of the process —conditioning, assisted extraction, separation, concentration, drying and packaging— and is **designed to operate with energy autonomy from renewable sources and with a closed-loop solvent-recovery circuit**. Its design also enables **cascade extraction**, in which the solid residue is automatically redirected in order to chain successive extractions and make the most of the biomass. By processing the freshly harvested material in the field, the transport of large quantities of water is avoided and the degradation of the fresh material is halted, yielding a final product that is dry, stable and ready for use.

The technology, protected by a patent application, has been developed at laboratory scale, where the process has been validated on various real agro-industrial by-products, such as olive leaf, grape pomace and pineapple by-products. The extracts obtained are applicable in the functional food, nutraceutical, cosmetic, pharmaceutical and biostimulant sectors. Companies interested in its commercial exploitation are sought.

VENTAJAS Y ASPECTOS INNOVADORES

ADVANTAGES OF THE TECHNOLOGY

Compared with extraction in fixed centralised facilities and with conventional portable equipment, this mobile unit offers the following advantages:

- **Eliminates logistics dependence and its costs:** by processing the freshly harvested biomass in the field itself, the transport of large quantities of water is avoided (fresh material usually contains 60–80% moisture) and transport costs —which in centralised models can amount to between 30% and 70% of the total cost— are eliminated.
- **Preserves the quality and reproducibility of the extract:** by minimising the time between harvesting and processing, the degradation (enzymatic, microbial and oxidative) that fresh material undergoes during transport and storage —capable of reducing the compounds of interest by between 20% and 50%— is halted, which translates into a higher-quality and more reproducible extract.
- **Makes the most of the biomass (cascade extraction):** the system chains several extractions on the same material automatically; the first conditions the plant matrix and improves the yield of the next, so that several value fractions are obtained from a single biomass and the overall yield increases.
- **Energy autonomy with intelligent management:** it operates without connection to the electricity grid thanks to its own renewable supply, and its control system adjusts or prioritises the stages according to the available energy, which makes it possible to operate in isolated areas or those with limited resources.

- **Sustainability — closed-loop solvent:** the extraction solvent is recovered and reused internally, reducing its consumption, losses and emissions to the exterior.
- **Final product that is dry, stable and ready to be marketed:** unlike mobile equipment that obtains only liquid extracts (unstable and perishable), this unit can incorporate a drying step that transforms the extract into a solid —preferably a powder— of greater stability and shelf life, suitable for direct distribution from source.
- **Notably reduces extraction times:** the use of assisted-extraction techniques makes it possible to obtain the extract in a fraction of the time required by traditional solid-liquid methods (usually 30–60 minutes).
- **Flexibility of operation and scaling:** the possibility of working continuously or in batches and of sizing the equipment at pilot or semi-industrial scale.
- **Versatility of application:** being adaptable to different types of biomass and target compounds, a single platform could serve several crops and products.
- **Lower carbon footprint:** avoiding the transport of moist biomass and using renewable energy points to a reduction in the carbon footprint of the process.
- **Revalorisation of by-products on site:** it transforms an agricultural residue —whose management is usually a cost— into a value-added product obtained in the field itself, opening up a possible new source of income.

INNOVATIVE ASPECTS OF THE TECHNOLOGY

The main innovative aspects of this technology are two: on the one hand, the integration of the entire processing line —from the fresh biomass to the dry product— within a single mobile and energy-autonomous platform; and, on the other, an automatic solid-residue return mechanism that makes integrated cascade extraction possible, without manual intervention.

The first aspect is the complete integration of the process within a mobile, autonomous unit. What is technically new is not each stage on its own —extracting, separating, concentrating or drying are known operations— but rather that all of them are physically linked and coordinated within a single unit capable of operating in the field itself, without connection to the grid. It is this integration that makes it possible to obtain a stable final product directly on site, something that earlier mobile systems did not achieve, as they were limited to partial operations or to liquid extracts. Moreover, because the biomass is processed in the very place where it is generated, the transport of large quantities of moist material is avoided and the by-product is transformed into a higher-value product in the field.

The second aspect is the automatic return of the solid residue to the reactor in order to chain extractions. In the usual methods, the plant material is discarded or treated separately after a first extraction; here, by contrast, it is automatically redirected to be subjected to a second solvent within the same cycle. The key lies in the fact that the first extraction modifies the structure of the plant matrix and facilitates the next, so that this chaining not only automates the process but also increases the overall recovery yield.

APLICACIONES DE LA OFERTA

This technology falls within the field of applied chemical engineering and the valorisation of plant biomass, specifically within mobile systems for the in situ processing of agricultural by-products and the obtaining of bioactive extracts. Owing to its cross-cutting nature, it is of interest both to the sectors that generate the biomass —potential users of the equipment— and to the target markets for the extracts obtained.

Biomass-generating sectors:

- Olive-oil sector and olive mills: pruning residues and by-products of the olive grove.
- Wine industry and wineries: pomace and winemaking by-products.
- Fruit and vegetable processing industry: high-moisture by-products, such as those derived from pineapple.
- Agricultural holdings, cooperatives and managers of agro-industrial by-products: valorisation of plant residues in the very place where they are generated.

Target markets for the extracts:

- Functional foods and nutraceuticals: antioxidant ingredients of natural origin.
- Cosmetics and dermatological pharmacy: active ingredients of plant origin.
- Pharmaceutical industry: bioactive compounds of interest.
- Biostimulants and crop protection: plant-based agricultural formulations.
- Cleaning and household-care products: ingredients of natural origin.

Additional potential uses:

- Natural pigments and colourants: cascade operation would make it possible to recover, in addition to the antioxidants, pigment fractions (e.g. chlorophyll) of interest as natural colourants.
- Other high-moisture agro-industrial by-products: possible extension to matrices such as citrus, tomato, spent coffee grounds or brewers' spent grain, among others.
- Active packaging and natural preservatives: use of the antioxidant extracts as additives to extend the preservation of foods.

The bioCir research group of the University of Alicante is seeking companies interested in incorporating this technology into their processes or in taking part in the subsequent stages of development and validation, by means of one of the following arrangements:

- **Patent licence:** assignment of the rights to use the technology to companies with the capacity for its implementation and commercial exploitation.
- **Technology transfer:** transmission of the associated technical knowledge (know-how) and of the support needed for its correct implementation in the partner's production environment.
- **Joint research and proof of concept:** collaboration for the assembly and validation of the integrated prototype at pilot scale and its subsequent scaling, as well as for the adaptation of the unit to the specific needs of the company. Given that the technology is at laboratory scale, this is the priority route in the short term.

Main areas of collaboration:

- Assembly and validation of the integrated prototype at pilot scale.
- Semi-industrial scaling of the mobile unit.
- Adaptation of the system to the by-products and plant matrices of interest to the partner.
- Optimisation of the processing line (assisted extraction, cascade extraction and drying) for specific products.
- Development of ingredients and formulations from the extracts obtained.

Company profiles sought:

- The olive-oil sector and olive mills, wineries and the wine industry, and the fruit and vegetable processing industry, as generators of biomass and potential users of the equipment.
 - Agricultural cooperatives and managers of agro-industrial by-products interested in valorising their residues on site.
 - Engineering companies and manufacturers of process equipment or agricultural machinery, for the development and production of the unit.
 - Companies in the functional food, nutraceutical, cosmetic and pharmaceutical fields, as well as in biostimulants, crop protection and natural-based cleaning products, as target markets for the extracts.
-
